Chapter 1

Computers Programming -First Class

Asst.Lect. Nariman Jabber Qasim

2017-2018

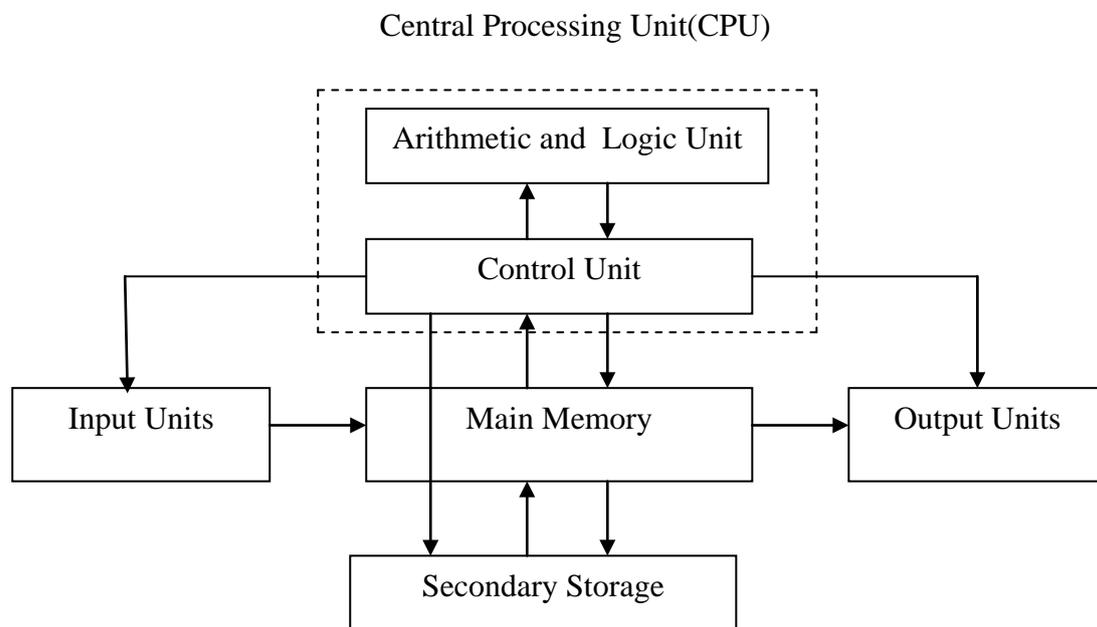

ENIAC

Introduced in 1946, ENIAC (Electronic Numerical Integrator and Computer) was the first general-purpose electronic computer. It was built for the United States military to calculate the paths of artillery shells. Physically, ENIAC was enormous, weighing more than 27,000 kilograms (60,000 pounds) and filling a large room. To process data, ENIAC used about 18,000 vacuum tubes, each the size of a small light bulb. The tubes burned out easily and had to be constantly replaced.

Computers Operations

All computers execute three basic operations:

1. Input data and instruction by input unit.
2. Save and process data and instruction by memory unit and central processing unit.
3. Output results and instruction by output unit.

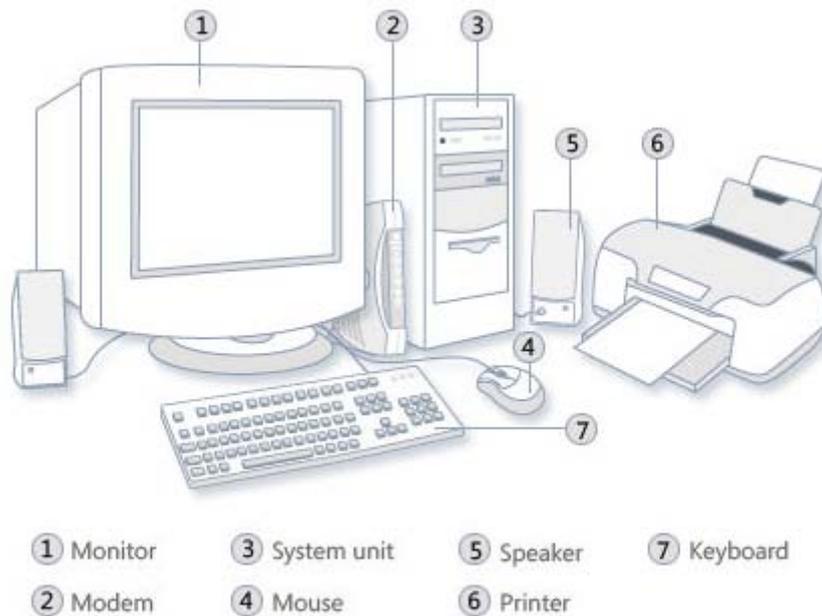

Computer Hardware Diagram

Computer Hardware

If you use a desktop computer, you might already know that there isn't any single part called the "computer". A computer is really a system of many parts working together. The physical parts, which you can see and touch, are collectively called hardware. (Software, on the other hand, refers to the instructions, or programs, that tell the hardware what to do.)

The following illustration shows the most common hardware in a desktop computer system. Your system might look a little different, but it probably has most of these parts. A laptop computer has similar parts but combines them into a single, notebook-sized package. Let's take a look at each of these parts.

Desktop computer system

Input / Output Units

- **Mouse**

A mouse is a small device used to point to and select items on your computer screen. Although mice come in many shapes, the typical mouse does look a bit like an actual mouse. It's small, oblong, and connected to the system unit by a long wire that resembles a tail. Some newer mice are wireless.

A mouse usually has two buttons: A primary button (usually the left button) and a secondary button. Many mice also have a wheel between the two buttons, which allows you to scroll smoothly through screens of information.

When you move the mouse with your hand, a pointer on your screen moves in the same direction. (The pointer's appearance might change depending on where it's positioned on your screen.) When you want to select an item, you point to the item and then click (press and release) the primary button. Pointing and clicking with your mouse is the main way to interact with your computer.

Mouse

- **Keyboard**

A keyboard is used mainly for typing text into your computer. Like the keyboard on a typewriter, it has keys for letters and numbers, but it also has special keys:

- The function keys, found on the top row, perform different functions depending on where they are used.
- The numeric keypad, located on the right side of most keyboards, allows you to enter numbers quickly.
- The navigation keys, such as the arrow keys, allow you to move your position within a document or webpage.

You can also use your keyboard to perform many of the same tasks you can perform with a mouse.

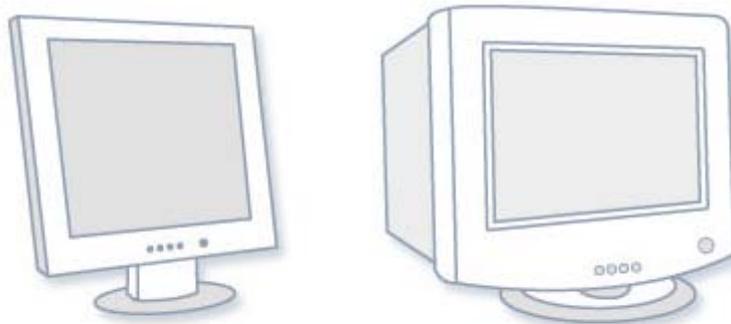

Keyboard

- **Monitor**

A monitor displays information in visual form, using text and graphics. The portion of the monitor that displays the information is called the screen. Like a television screen, a computer screen can show still or moving pictures.

There are two basic types of monitors: CRT (cathode ray tube) monitors and the newer LCD (liquid crystal display) monitors. Both types produce sharp images, but LCD monitors have the advantage of being much thinner and lighter.

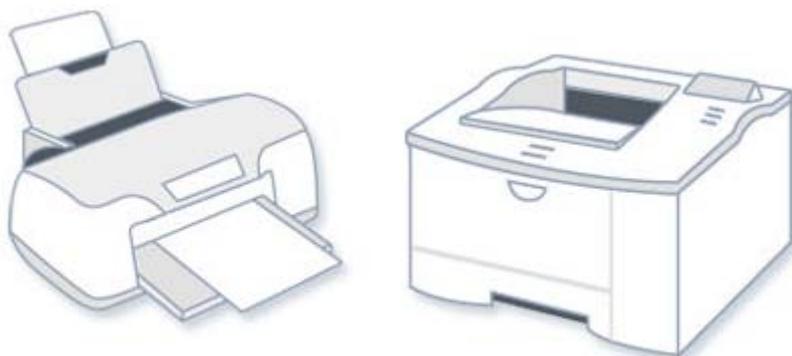

LCD monitor (left); CRT monitor (right)

- **Printer**

A printer transfers data from a computer onto paper. You don't need a printer to use your computer, but having one allows you to print e-mail, cards, invitations, announcements, and other material. Many people also like being able to print their own photos at home.

The two main types of printers are inkjet printers and laser printers. Inkjet printers are the most popular printers for the home. They can print in black and white or in full color and

can produce high-quality photographs when used with special paper. Laser printers are faster and generally better able to handle heavy use.

Inkjet printer (left); laser printer (right)

- **Speakers**

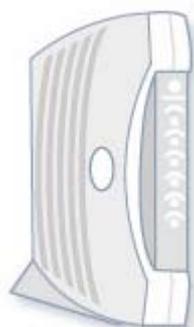

Speakers are used to play sound. They can be built into the system unit or connected with cables. Speakers allow you to listen to music and hear sound effects from your computer.

Computer speakers

- **Modem**

To connect your computer to the Internet, you need a modem. A modem is a device that sends and receives computer information over a telephone line or high-speed cable. Modems are sometimes built into the system unit, but higher-speed modems are usually separate components.

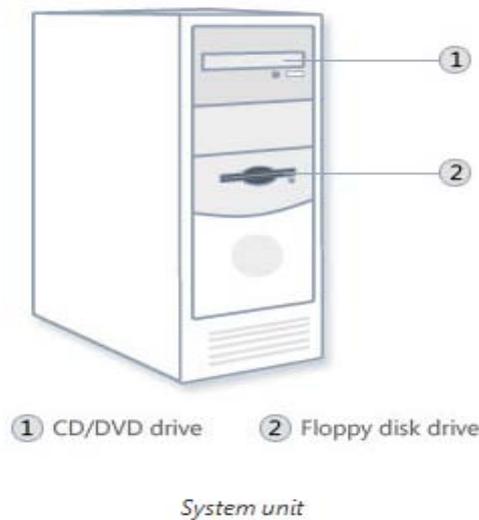

Cable modem

System Units

The system unit is the core of a computer system. Usually it's a rectangular box placed on or underneath your desk. Inside this box are many electronic components that process information. The most important of these components is the **Central Processing Unit (CPU), or Microprocessor**, which acts as the "brain" of your computer. Another component is **Random Access Memory (RAM)**, which temporarily stores information that the CPU uses while the computer is on. The information stored in RAM is erased when the computer is turned off.

Almost every other part of your computer connects to the system unit using cables. The cables plug into specific ports (openings), typically on the back of the system unit. Hardware that is not part of the system unit is sometimes called a peripheral device or device.

- **Central Processing Unit (CPU):** the main circuit chip in computer, it performs most of the calculations necessary to run computer. CPU speed measured by account of instructions that can execute in one secant, usually measured in (MHz). CPU contents two units:

1. **Control Unit (CU).**
2. **Arithmetic and Logic Unit (ALU).**

1. Control Unit (CU).

This unit control or supervised to all parts of computers such as:

- Control operation of transfers data and instruction from input unit to memory and from memory to output unit.
- Control operation of account executable instructions on ALU.
- Basic work of CU is interpreter the instructions that is mean data oriented to specific location on ALU. for example: if the instruction is (B+C) the B,C values transfers to (Adder) part, if the instruction is (BxC) the B,C values transfers to (Multiplier) part,

2. Arithmetic and Logic Unit (ALU).

This unit execute the following operations:

- Mathematical operations such as: add (+), abstract (-), multiplier (×), divide (÷).
- Logical operations: this is basic to account comparisons to choose true or false specific case, such as >, <, >=, <=, <>, = as a result of these comparisons specific instructions may be executable.
- Merge number of simple comparisons by specific tools such as: AND, OR, NOT.

What are Registers? CPU unit can do the most of it is work by using registers, registers are small and speed storage units, used on ALU and CU. the CPU contains many types of registers such as: *Accumulator, Data, address, program counter, instruction, statues, general purpose registers.*

What are Buses? The command received on CPU through buses, where the buses use to transfer electric impulse between different computer parts, as code signals therefore the buses are data path between the CPU and other computer parts such as input, output, and storage units. The one bus made of set of metal wires that sprawled over mother board. The types of buses are:

1. **Data Bus:** use to transfer data.
2. **Address Bus:** use to transfer storage location addresses.
3. **Control Bus:** use to transfer control signal and operation timer between computer parts.

System Board or Mother Board: the important part on computer loading the CPU, memories, and control circuit. it is allows to computer parts to exchange data to perform the required work, and coordinate computer parts, and memory organization.

- **Main memory:** refers usually to Random Access Memory (RAM) the temporary storage area the computer uses to run programs and store data .information store in RAM is temporary and is designed to be erased when computer turn off.**RAM** is a general indication of performance that is measured either in megabytes (MB) or gigabytes (GB): the larger the number, the faster some programs will run. Memory is set of electronic circuit named (**Cells**), each cell store 0 or 1, like (on or off),the single cell content named (**BIT**) which represent basic unit in process data, because all data transfer to set of bits in digital computers.(**BYTE**) term for eight Bit i.e:

$$1 \text{ Byte} = 8 \text{ Bit}$$

- Memory Capacity

Memory capacity units measured in **kilo Byte** which abstract by (**KB**) where:

$$\text{KB} = 2^{10} \text{ Bytes} = 1024 \text{ Bytes}$$

In memories has large capacity measured in **Mega Byte** which abstract by (**MB**) where:

$$1 \text{ MB} = 2^{20} \text{ Bytes} = 1048576 \text{ Bytes}$$

In larger memories capacity measured in **Giga Byte** which abstract by (**GB**) where:

$$1 \text{ GB} = 2^{30} \text{ Bytes} = 1073741824 \text{ Bytes}$$

In largest memories capacity measured in **Tiara Byte** which abstract by (**TB**) where:

$$1 \text{ TB} = 2^{40} \text{ Bytes} = 1099511627776 \text{ Bytes}$$

- **Memory Speed**

Memory speed measured in **WRITE** speed where write mean translate data operations from CPU to main memory also measured in **READ** speed where read mean translate data operations from main memory to CPU. read and write operations in memory named by **Access**. Because read and write operations generated by CPU therefore memory speed equal almost CPU speed.

- **Types of Memory**

Random Access Memory (RAM): in this kind of memory can read and write on it generated by CPU. This kind of memory used by user to store his programs on it. this memory is temporary storage ends when the process is end or when split electric power.

Read Only Memory (ROM): in this kind of memory can read only from it generated by CPU, but cannot write on it from this unit because store specific computer system software on this kinds of memories, such as: BIOS ,Start up Routine, Input/ output routine, Interpreter. This memory do not miss it is contents where split electric power.

What is BIOS?**BIOS (Basic Input Output System)**:is a software that is built into computers and that is run when the computer first turn on. among other things this software starts the operating system and support transfer information between hard ware devices. BIOS is part of your computer's hardware and is separate from Windows.

What is CMOS? **Complementary metal-oxide semiconductor, or CMOS**, typically refers to a battery-powered memory chip in your computer that stores startup information. Your computer's [basic input/output system \(BIOS\)](#) uses this information when starting your computer.
